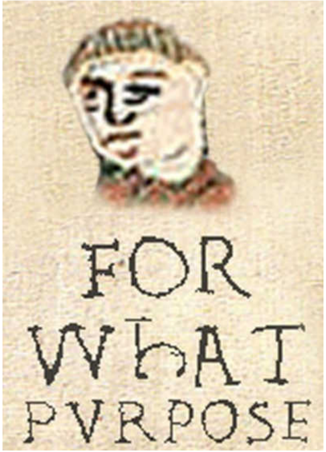
What?



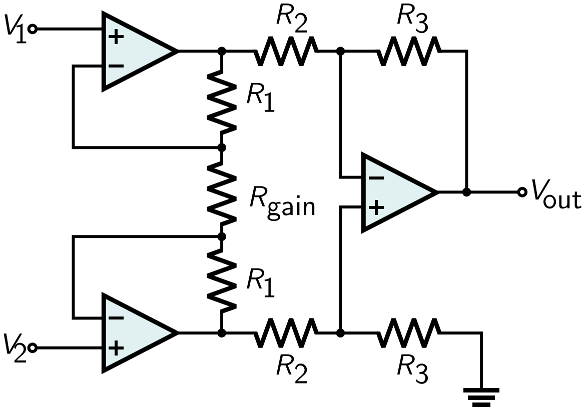
Why?

Roots as early as the 1970's at MIT

- Guy L. Steele Jr.
- Gerald J. Sussman
- Richard Stallman

More recently:

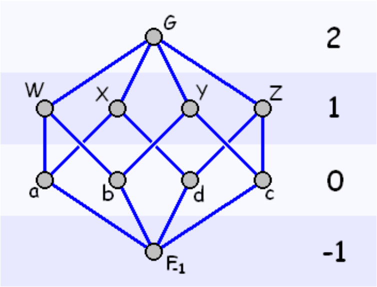
- Alexey Radul



```
(define (map f xs)
  (cond ((null? xs) ’())
        (else (cons (f (car xs))
                    (map f (cdr xs))))))
```

And then

- Edward Kmett



$$x \leq y \implies f(x) \leq f(y)$$

Propagators

The *propagator model* is a model of computation
We model computations as *propagator networks*

The *propagator model* is a model of computation
We model computations as *propagator networks*

Propagator networks:

- are extremely expressive
- lend themselves to parallel and distributed evaluation
- allow different strategies of problem-solving to seamlessly cooperate

A propagator network comprises

- cells
- propagators
- connections between cells and propagators

$$z \leftarrow x + y$$

$$z = x + y$$

$$7 = x + 4$$

$$7 = 3 + 4$$

$$z = x + y$$

$$z \leftarrow x + y$$

$$x \leftarrow z - y$$

$$y \leftarrow z - x$$

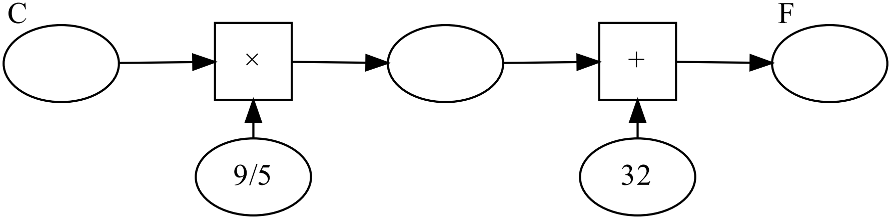
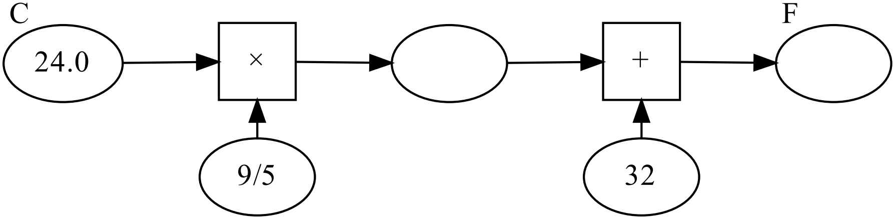
Propagators let us express multi-directional relationships!

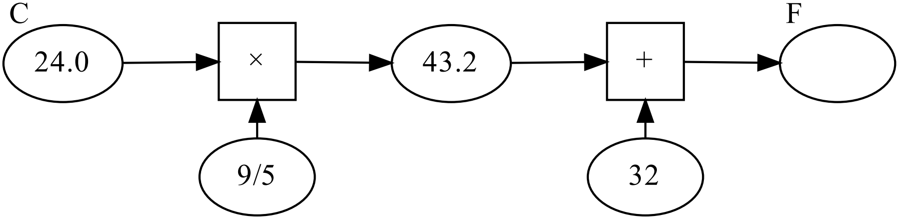
$$^\circ F = {^\circ C} \times \frac{9}{5} + 32$$



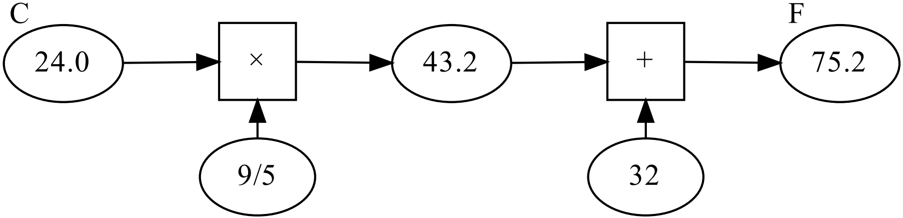
$$^\circ F = {^\circ C} \times \frac{9}{5} + 32$$



$$°F = °C \times \frac{9}{5} + 32$$

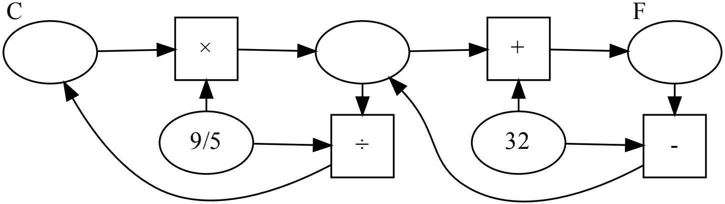


$$^{\circ}F = {^{\circ}C} \times \frac{9}{5} + 32$$



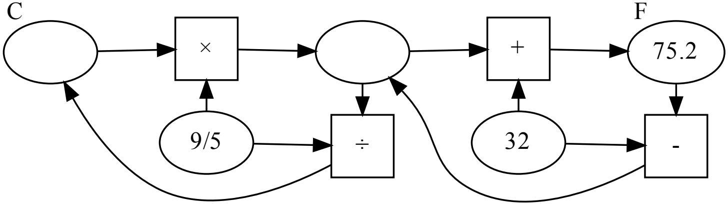
$$^\circ F = {^\circ C} \times \frac{9}{5} + 32$$

$$^\circ C = ({^\circ F} - 32) \div \frac{9}{5}$$



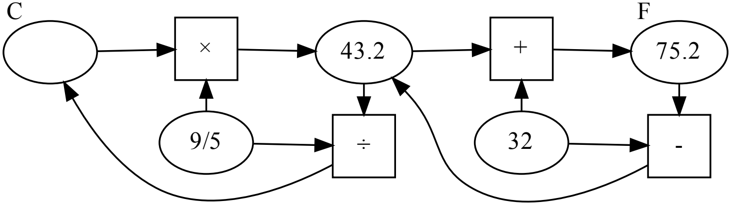
$$^\circ F = {^\circ C} \times \frac{9}{5} + 32$$

$$^\circ C = ({^\circ F} - 32) \div \frac{9}{5}$$



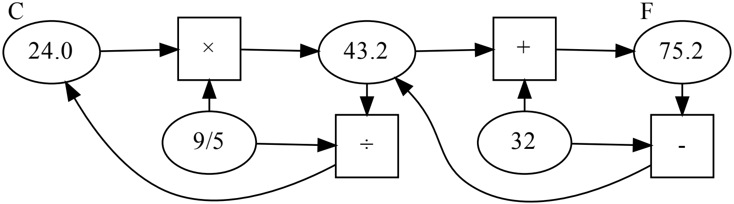
$$^\circ F = {^\circ C} \times \frac{9}{5} + 32$$

$$^\circ C = (^\circ F - 32) \div \frac{9}{5}$$



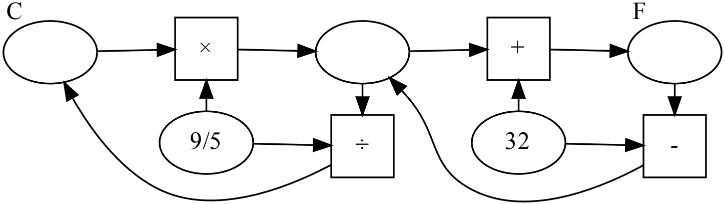
$$°F = °C \times \frac{9}{5} + 32$$

$$°C = (°F - 32) \div \frac{9}{5}$$



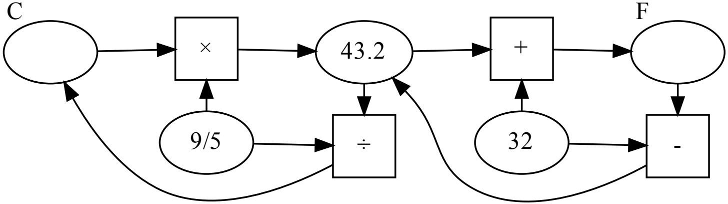
$$^\circ F = {^\circ C} \times \frac{9}{5} + 32$$

$$^\circ C = ({^\circ F} - 32) \div \frac{9}{5}$$



$$°F = °C \times \frac{9}{5} + 32$$

$$°C = (°F - 32) \div \frac{9}{5}$$



$$^\circ F = {}^\circ C \times \frac{9}{5} + 32$$

$$^\circ C = ({}^\circ F - 32) \div \frac{9}{5}$$

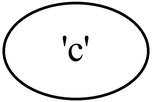
We can combine networks into larger networks!

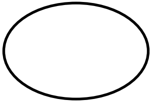
?

What types are the values of the cells?



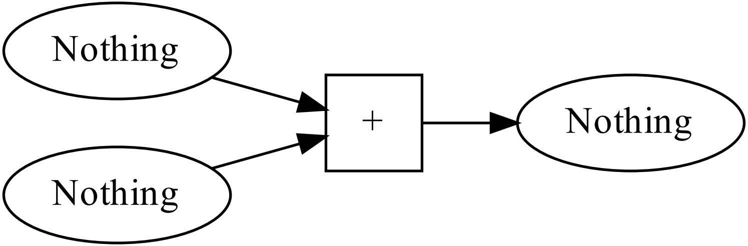
'c'

3



Cells store *information about a value*

```
data Maybe a = Nothing | Just a
```



Nothing

Contradiction

```haskell
data Perhaps a = Unknown | Known a | Contradiction
data Perhaps a = Unknown | Known a | Contradiction

instance Eq a => Monoid (Perhaps a) where
  mempty = Unknown

  mappend Unknown x           = x
  mappend x       Unknown     = x
  mappend Contradiction _     = Contradiction
  mappend _     Contradiction = Contradiction
  mappend (Known a) (Known b) =
    if a == b
      then Known a
      else Contradiction
```

We need commutativity!

$$x \oplus y = y \oplus x$$

We need commutativity!

$$x \oplus y = y \oplus x$$

List append is not commutative!

```
[1,2,3] <> [4,5,6] == [1,2,3,4,5,6]
[4,5,6] <> [1,2,3] == [4,5,6,1,2,3]
```

We need a commutative monoid

What about addition?

$$x + y = y + x$$

We need idempotence!

$$x \oplus x = x$$

We need an idempotent, commutative monoid.
This structure is called a *join-semilattice*

Associativity

$$(x \vee y) \vee z = x \vee (y \vee z)$$

Commutativity

$$x \vee y = y \vee x$$

Idempotence

$$x \vee x = x$$

Partial information that supports merging!

Other examples?

$$[1, 5]$$

$$[1, 5] <> [2, 7] = [2, 5]$$

$$\{True,\ False\}$$

TODO set intersection examples
